==========

上篇文章概述了FFmpeg的libavcodec中HEVC（H.265）解码器的结构；从这篇文章开始，具体研究HEVC解码器的源代码。本文分析HEVC解码器中解析器（Parser）部分的源代码。这部分的代码用于分割HEVC的NALU，并且解析SPS、PPS、SEI等信息。解析HEVC码流（对应AVCodecParser结构体中的函数）和解码HEVC码流（对应AVCodec结构体中的函数）的时候都会调用该部分的代码完成相应的功能。

函数调用关系图

FFmpeg HEVC解析器（Parser）部分在整个HEVC解码器中的位置如下图所示。

http://blog.csdn.net/leixiaohua1020

单击查看更清晰的大图

从图中可以看出，HEVC解析器调用了parse_nal_units()，HEVC解码器调用了decode_nal_units()，而上述两个函数都调用了下面几个解析函数：

ff_hevc_decode_nal_vps()：解析VPS。

ff_hevc_decode_nal_sps()：解析SPS。

ff_hevc_decode_nal_pps()：解析PPS。

ff_hevc_decode_nal_sei()：解析SEI。

下文将会分别这几个函数。

ff_hevc_decoder

ff_hevc_decoder是HEVC解码器对应的AVCodec结构体。该结构体的定义位于libavcodec\hevc.c，如下所示。

```cpp
AVCodec ff_hevc_decoder = {
    .name                  = "hevc",
    .long_name             = NULL_IF_CONFIG_SMALL("HEVC (High Efficiency Video Coding)"),
    .type                  = AVMEDIA_TYPE_VIDEO,
    .id                    = AV_CODEC_ID_HEVC,
    .priv_data_size        = sizeof(HEVCContext),
    .priv_class            = &hevc_decoder_class,
    .init                  = hevc_decode_init,
    .close                 = hevc_decode_free,
    .decode                = hevc_decode_frame,
    .flush                 = hevc_decode_flush,
    .update_thread_context = hevc_update_thread_context,
    .init_thread_copy      = hevc_init_thread_copy,
    .capabilities          = CODEC_CAP_DR1 | CODEC_CAP_DELAY |
                             CODEC_CAP_SLICE_THREADS | CODEC_CAP_FRAME_THREADS,
    .profiles              = NULL_IF_CONFIG_SMALL(profiles),
};
```

从源代码中可以看出，HEVC解码器的解码函数是hevc_decode_frame()。由于本文主要分析HEVC解析器，所以不对解码函数进行分析。在这里只需要知道hevc_decode_frame()调用了decode_nal_units()，而decode_nal_units()最终调用了ff_hevc_decode_nal_sps()等解析函数即可。

ff_hevc_parser

ff_hevc_parser是HEVC解析器对应的AVCodecParser结构体。该结构体的定义位于libavcodec\hevc_parser.c，如下所示。

```cpp
AVCodecParser ff_hevc_parser = {
    .codec_ids      = { AV_CODEC_ID_HEVC },
    .priv_data_size = sizeof(HEVCParseContext),
    .parser_init    = hevc_init,
    .parser_parse   = hevc_parse,
    .parser_close   = hevc_close,
    .split          = hevc_split,
};
```

从源代码可以看出，HEVC解析器的初始化函数是hevc_init()，解析函数是hevc_parse()，关闭函数是hevc_close()。

hevc_init()

hevc_init()是HEVC解析器的初始化函数，该函数的定义如下所示。

```cpp
static int hevc_init(AVCodecParserContext *s)
{
    HEVCContext  *h  = &((HEVCParseContext *)s->priv_data)->h;
    h->HEVClc = av_mallocz(sizeof(HEVCLocalContext));
    h->skipped_bytes_pos_size = INT_MAX;

    return 0;
}
```

可以看出hevc_init()简单地给内部成员变量分配了内存。

hevc_close()

hevc_close()是HEVC解析器的关闭函数，该函数的定义如下所示。

```cpp
static void hevc_close(AVCodecParserContext *s)
{
    int i;
    HEVCContext  *h  = &((HEVCParseContext *)s->priv_data)->h;
    ParseContext *pc = &((HEVCParseContext *)s->priv_data)->pc;

    av_freep(&h->skipped_bytes_pos);
    av_freep(&h->HEVClc);
    av_freep(&pc->buffer);

    for (i = 0; i < FF_ARRAY_ELEMS(h->vps_list); i++)
        av_buffer_unref(&h->vps_list[i]);
    for (i = 0; i < FF_ARRAY_ELEMS(h->sps_list); i++)
        av_buffer_unref(&h->sps_list[i]);
    for (i = 0; i < FF_ARRAY_ELEMS(h->pps_list); i++)
        av_buffer_unref(&h->pps_list[i]);

    av_buffer_unref(&h->current_sps);
    h->sps = NULL;

    for (i = 0; i < h->nals_allocated; i++)
        av_freep(&h->nals[i].rbsp_buffer);
    av_freep(&h->nals);
    h->nals_allocated = 0;
}
```

可以看出hevc_close()释放了内部成员变量的内存。

hevc_parse()

hevc_parse()是HEVC解析器中最关键的解析函数。该函数的定义如下所示。

```cpp
/*
 * 解析码流
 *
 * 注释：雷霄骅
 * leixiaohua1020@126.com
 * http://blog.csdn.net/leixiaohua1020
 */
static int hevc_parse(AVCodecParserContext *s,
                      AVCodecContext *avctx,
                      const uint8_t **poutbuf, int *poutbuf_size,
                      const uint8_t *buf, int buf_size)
{
    int next;
    ParseContext *pc = &((HEVCParseContext *)s->priv_data)->pc;
    //PARSER_FLAG_COMPLETE_FRAMES为1的时候说明传入的就是完整的1帧数据
    //这时候不用再分割NALU
    //PARSER_FLAG_COMPLETE_FRAMES为0的时候说明传入的是任意一段数据
    //需要先分离出完整的NALU
    if (s->flags & PARSER_FLAG_COMPLETE_FRAMES) {
        next = buf_size;
    } else {
        //分割NALU
        //通过查找起始码0x000001的方法
        next = hevc_find_frame_end(s, buf, buf_size);
        //合并
        if (ff_combine_frame(pc, next, &buf, &buf_size) < 0) {
            *poutbuf      = NULL;
            *poutbuf_size = 0;
            return buf_size;
        }
    }
    //解析NALU内容（不解码）
    parse_nal_units(s, avctx, buf, buf_size);

    *poutbuf      = buf;
    *poutbuf_size = buf_size;
    return next;
}
```

从源代码可以看出，hevc_parse()主要做了两步工作：

（1）判断传入的flags 中是否包含PARSER_FLAG_COMPLETE_FRAMES。如果包含，则说明传入的是完整的一帧数据，不作任何处理；如果不包含，则说明传入的不是完整的一帧数据而是任意一段HEVC数据，则需要调用hevc_find_frame_end()通过查找“起始码”（0x00000001或者0x000001）的方法，分离出完整的一帧数据。

（2）调用parse_nal_units()完成了NALU的解析工作。

下面分别看一下这两步中的两个函数。

hevc_find_frame_end()

hevc_find_frame_end()用于从HEVC码流中分离出完整的NALU。该函数的定义位于libavcodec\hevc_parser.c，如下所示。

```cpp
/**
 * Find the end of the current frame in the bitstream.
 * @return the position of the first byte of the next frame, or END_NOT_FOUND
 */
//分割NALU
static int hevc_find_frame_end(AVCodecParserContext *s, const uint8_t *buf,
                               int buf_size)
{
    int i;
    ParseContext *pc = &((HEVCParseContext *)s->priv_data)->pc;
    //一个一个字节进行处理
    for (i = 0; i < buf_size; i++) {
        int nut;
        //state64可以存8个字节
        //buf[i]存入state64
        pc->state64 = (pc->state64 << 8) | buf[i];

        //起始码定义#define START_CODE 0x000001
        //state64右移24bit之后，再对比是否为起始码0x000001
        if (((pc->state64 >> 3 * 8) & 0xFFFFFF) != START_CODE)
            continue;
        //找到起始码之后
        /*
         * 此时state64内容如下：
         *               |      Start Code    | NALU Header |
         * |------|------|------|------|------|------|------|------|
         *
         *               |  buf |  buf |  buf |  buf |  buf | buf  |
         *               | [t-5]| [t-4]| [t-3]| [t-2]| [t-1]|  [t] |
         *
         * Start Code:
         * 0x000001
         *
         * NALU Header:
         * forbidden_zero_bit: 1bit。取值0。
         * nal_unit_type: 6 bit。NALU类型。
         * nuh_layer_id: 6 bit。目前取值为0（保留以后使用）.
         * nuh_temporal_id_plus1: 3 bit。减1后为NALU时域层标识号TemporalID。
         *
         */
        //state64右移16bit之后，state64最低字节为起始码后面的1Byte。即为NALU Header的前一个字节
        //NALU Header的前一个字节中，第1bit为forbidden_zero_bit，取值为0；
        //2-7bit为nal_unit_type；第8bit为nuh_layer_id，取值为0。

        //在这里state64右移(16+1)bit，然后相与0x3F(00111111)
        //即得到了nal_unit_type
        nut = (pc->state64 >> 2 * 8 + 1) & 0x3F;

        // Beginning of access unit
        if ((nut >= NAL_VPS && nut <= NAL_AUD) || nut == NAL_SEI_PREFIX ||
            (nut >= 41 && nut <= 44) || (nut >= 48 && nut <= 55)) {
            if (pc->frame_start_found) {
                pc->frame_start_found = 0;
                //返回起始码开始位置
                return i - 5;
            }
        } else if (nut <= NAL_RASL_R ||
                   (nut >= NAL_BLA_W_LP && nut <= NAL_CRA_NUT)) {
            int first_slice_segment_in_pic_flag = buf[i] >> 7;
            if (first_slice_segment_in_pic_flag) {
                if (!pc->frame_start_found) {
                    pc->frame_start_found = 1;
                } else { // First slice of next frame found
                    pc->frame_start_found = 0;
                    //返回起始码开始位置
                    return i - 5;
                }
            }
        }
    }

    return END_NOT_FOUND;
}
```

从源代码可以看出，hevc_find_frame_end()使用ParseContext中的state64临时缓存读取的字节。state64是一个uint64_t类型的变量，一共可以存储8Byte的数据。函数体的for()循环一次读取一个字节，读取完成后将该字节放入state64变量中；接着与起始码“0x000001”进行比较，如果不相等则继续读取，如果相等的话则提取NALU Header中nal_unit_type信息做相应处理后返回起始码开始的位置。

parse_nal_units()

parse_nal_units()用于解析一些NALU（VPS、SPS、PPS）的信息。该函数的定义位于libavcodec\hevc_parser.c，如下所示。

```cpp
/**
 * Parse NAL units of found picture and decode some basic information.
```

```
 *
 * @param s parser context.
 * @param avctx codec context.
 * @param buf buffer with field/frame data.
 * @param buf_size size of the buffer.
 *
 * 解析NALU内容（不解码）
 * 注释：雷霄骅
 * leixiaohua1020@126.com
 * http://blog.csdn.net/leixiaohua1020
 *
 */
static inline int parse_nal_units(AVCodecParserContext *s, AVCodecContext *avctx,
                      const uint8_t *buf, int buf_size)
{
    HEVCContext   *h  = &((HEVCParseContext *)s->priv_data)->h;
    GetBitContext *gb = &h->HEVClc->gb;
    SliceHeader   *sh = &h->sh;
    const uint8_t *buf_end = buf + buf_size;
    int state = -1, i;
    HEVCNAL *nal;

    /* set some sane default values */
    s->pict_type         = AV_PICTURE_TYPE_I;
    s->key_frame         = 0;
    s->picture_structure = AV_PICTURE_STRUCTURE_UNKNOWN;

    h->avctx = avctx;

    if (!buf_size)
        return 0;

    if (h->nals_allocated < 1) {
        HEVCNAL *tmp = av_realloc_array(h->nals, 1, sizeof(*tmp));
        if (!tmp)
            return AVERROR(ENOMEM);
        h->nals = tmp;
        memset(h->nals, 0, sizeof(*tmp));
        h->nals_allocated = 1;
    }

    nal = &h->nals[0];

```

从源代码可以看出，parse_nal_units()根据nal_unit_type的不同，调用不同的解析函数进行处理。例如：

a)解析VPS的时候调用ff_hevc_decode_nal_vps()

b)解析SPS的时候调用ff_hevc_decode_nal_sps()

c)解析PPS的时候调用ff_hevc_decode_nal_pps()

d)解析SEI的时候调用ff_hevc_decode_nal_sei()

e)解析SS Header的一部分信息。

下文简单分析这几种NALU的解析函数。

ff_hevc_decode_nal_vps()

目前还没有研究过VPS，所以没有分析该函数。

ff_hevc_decode_nal_sps()

ff_hevc_decode_nal_sps()用于解析HEVC码流中的SPS。该函数的定义位于libavcodec\hevc_ps.c，如下所示。

```cpp
//解析SPS
int ff_hevc_decode_nal_sps(HEVCContext *s)
{
    const AVPixFmtDescriptor *desc;
    GetBitContext *gb = &s->HEVClc->gb;
    int ret = 0;
    unsigned int sps_id = 0;
    int log2_diff_max_min_transform_block_size;
    int bit_depth_chroma, start, vui_present, sublayer_ordering_info;
    int i;

    HEVCSPS *sps;
    AVBufferRef *sps_buf = av_buffer_allocz(sizeof(*sps));

    if (!sps_buf)
        return AVERROR(ENOMEM);
    sps = (HEVCSPS*)sps_buf->data;

    av_log(s->avctx, AV_LOG_DEBUG, "Decoding SPS\n");

    // Coded parameters
    // 当前引用的VPS的ID
    sps->vps_id = get_bits(gb, 4);
    if (sps->vps_id >= MAX_VPS_COUNT) {
        av_log(s->avctx, AV_LOG_ERROR, "VPS id out of range: %d\n", sps->vps_id);
        ret = AVERROR_INVALIDDATA;
        goto err;
    }

    if (!s->vps_list[sps->vps_id]) {
        av_log(s->avctx, AV_LOG_ERROR, "VPS %d does not exist\n",
```

```
                sps->vps_id);
        ret = AVERROR_INVALIDDATA;
        goto err;
    }
    //时域子层的最大数目

解析SPS源代码并不是很有“技术含量”。只要参考ITU-T的《HEVC标准》就可以理解了，不再做过多详细的分析。

ff_hevc_decode_nal_pps()

ff_hevc_decode_nal_pps()用于解析HEVC码流中的PPS。该函数的定义位于libavcodec\hevc_ps.c，如下所示。

```cpp
//解析PPS
int ff_hevc_decode_nal_pps(HEVCContext *s)
{
    GetBitContext *gb = &s->HEVClc->gb;
    HEVCSPS      *sps = NULL;
    int pic_area_in_ctbs;
    int log2_diff_ctb_min_tb_size;
    int i, j, x, y, ctb_addr_rs, tile_id;
    int ret = 0;
    unsigned int pps_id = 0;

    AVBufferRef *pps_buf;
    HEVCPPS *pps = av_mallocz(sizeof(*pps));

    if (!pps)
        return AVERROR(ENOMEM);

    pps_buf = av_buffer_create((uint8_t *)pps, sizeof(*pps),
                               hevc_pps_free, NULL, 0);
    if (!pps_buf) {
        av_freep(&pps);
        return AVERROR(ENOMEM);
    }

    av_log(s->avctx, AV_LOG_DEBUG, "Decoding PPS\n");

    // Default values
    // 默认值
    pps->loop_filter_across_tiles_enabled_flag = 1;
    pps->num_tile_columns                      = 1;
    pps->num_tile_rows                         = 1;

        }
    }

    if (get_bits_left(gb) < 0) {
        av_log(s->avctx, AV_LOG_ERROR,
               "Overread PPS by %d bits\n", -get_bits_left(gb));
        goto err;
    }

    av_buffer_unref(&s->pps_list[pps_id]);
    s->pps_list[pps_id] = pps_buf;

    return 0;

err:
    av_buffer_unref(&pps_buf);
    return ret;
}
```

与解析SPS类似，解析PPS源代码并不是很有“技术含量”。只要参考ITU-T的《H.264标准》就可以理解了，不再做过多详细的分析。

ff_hevc_decode_nal_sei()

ff_hevc_decode_nal_sei()用于解析HEVC码流中的SEI。该函数的定义位于libavcodec\hevc_sei.c，如下所示。

```cpp
//解析SEI
int ff_hevc_decode_nal_sei(HEVCContext *s)
{
    int ret;

    do {
        //解析SEI信息
        ret = decode_nal_sei_message(s);
        if (ret < 0)
            return(AVERROR(ENOMEM));
    } while (more_rbsp_data(&s->HEVClc->gb));
    return 1;
}
```

从源代码可以看出，ff_hevc_decode_nal_sei()在一个do while循环中调用了另外一个函数decode_nal_sei_message()解析SEI信息。

decode_nal_sei_message()

decode_nal_sei_message()用于解析SEI信息，它的定义如下。

```cpp
//解析SEI信息
static int decode_nal_sei_message(HEVCContext *s)
{
    GetBitContext *gb = &s->HEVClc->gb;

    int payload_type = 0;
    int payload_size = 0;
    int byte = 0xFF;
    av_log(s->avctx, AV_LOG_DEBUG, "Decoding SEI\n");

    while (byte == 0xFF) {
        byte          = get_bits(gb, 8);
        payload_type += byte;
    }
    byte = 0xFF;
    while (byte == 0xFF) {
        byte          = get_bits(gb, 8);
        payload_size += byte;
    }
    if (s->nal_unit_type == NAL_SEI_PREFIX) {
        if (payload_type == 256 /*&& s->decode_checksum_sei*/) {
            decode_nal_sei_decoded_picture_hash(s);
        } else if (payload_type == 45) {
            decode_nal_sei_frame_packing_arrangement(s);
        } else if (payload_type == 47) {
            decode_nal_sei_display_orientation(s);
        } else if (payload_type == 1){
            int ret = decode_pic_timing(s);
            av_log(s->avctx, AV_LOG_DEBUG, "Skipped PREFIX SEI %d\n", payload_type);
            skip_bits(gb, 8 * payload_size);
            return ret;
        } else if (payload_type == 129){
            active_parameter_sets(s);
            av_log(s->avctx, AV_LOG_DEBUG, "Skipped PREFIX SEI %d\n", payload_type);
        } else {
            av_log(s->avctx, AV_LOG_DEBUG, "Skipped PREFIX SEI %d\n", payload_type);
            skip_bits(gb, 8*payload_size);
        }
    } else { /* nal_unit_type == NAL_SEI_SUFFIX */
        if (payload_type == 132 /* && s->decode_checksum_sei */)
            decode_nal_sei_decoded_picture_hash(s);
        else {
            av_log(s->avctx, AV_LOG_DEBUG, "Skipped SUFFIX SEI %d\n", payload_type);
            skip_bits(gb, 8 * payload_size);
        }
    }
    return 1;
}
```

从源代码可以看出，decode_nal_sei_message()根据不同的payload_type调用不同的函数进行处理，例如调用decode_nal_sei_decoded_picture_hash()，decode_nal_sei_frame_packing_arrangement()，decode_nal_sei_display_orientation()等等。
